

Last time, highlighted role of one-row systems ("transfer matrices") T

with entries $T_{i,j}^{k,l}$

in understanding partition function Z . (e.g. toroidal boundary conditions)

$$Z = \text{Trace}_{V^{\otimes N}} ((\text{trace}_V(T))^M)$$

where $T \in \text{End}(V \otimes V^{\otimes N})$

Do this analysis, by focusing on particularities of given system.

In case of 6-vertex model with toroidal boundary conds., analyzing $\underbrace{\text{trace}_V(T)}_{\substack{!! \\ A}} \in \text{End}(V^{\otimes N})$

Done by Lieb + Sutherland (1967)

"transfer matrix"

Alluded to this methodology at end of last time -

use path model of transfer matrices, A breaks up into blocks according to # of paths above + below row. Use method (Bethe Ansatz) to solve for all e-values (distinct) and their e-vectors.

Result: Write $A = P A_{\text{diag}} P^{-1}$ P : matrix of eigenvectors
 A_{diag} : e-values (distinct)

(in special case where 6 weights are symmetric upon reversing arrows, so have 3 parameters "field-free case")

In particular, turns out P independent of a parameter. Call it x_i in row i .

Since $A_{\text{diag}}(x_1)$ commutes with $A_{\text{diag}}(x_2)$ then $A(x_1)$ and $A(x_2)$

commute: $A(x_1)A(x_2) = A(x_2)A(x_1)$ "transfer matrices commute"

Q: Is this reasoning reversible?

A: Amazingly, it is reversible and applies to arbitrary boundary conditions.

In section 9.5 of Baxter's book, he gives list of 6 sufficient conditions for determining e-values of general b-vertex model transfer matrix:

Steps (i) + (ii) : Prove transfer matrices commute.

Step (iii) : Show transfer matrices are entire functions of ex. parameter.

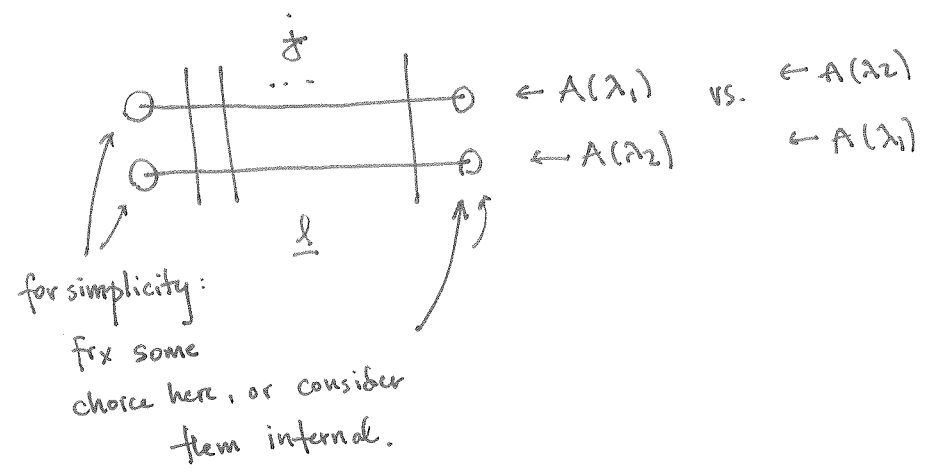

etc.

So question becomes - Is there a way to ensure (i.e. provide sufficient conds. for...) parametrized transfer matrices commute?

Example SE/NW: 1 NE/SW: λ NS/EW: $1 - q\lambda / 1 - q^{-1}\lambda$ λ : arb. ex. param.
 q : $\neq 0$ ex. param.
 think: λ : parameter in question.

Proposition: $A(\lambda_1)A(\lambda_2) = A(\lambda_2)A(\lambda_1)$ for any choice of λ_1, λ_2 .

proof strategy: pictorial.
 For any choice of \vec{j}, \vec{l}

Brilliant idea (Yang, Baxter):

Swapping of transfer matrices follows from mini-identity of partition functions:

Yang-Baxter equation: Seek a solution ~~R~~ R'' : set of weights encoded in matrix so that for any choice of arrows a, b, c, d, e, f :

$$Z \left(\begin{array}{c} b \\ \diagdown \\ R'' \\ \diagup \\ a \end{array} \begin{array}{c} \text{---} \\ | \\ R(\lambda_1) \\ | \\ \text{---} \\ | \\ R(\lambda_2) \\ | \\ f \end{array} \begin{array}{c} c \\ \text{---} \\ | \\ d \\ \text{---} \\ | \\ e \end{array} \right) = Z \left(\begin{array}{c} b \\ \text{---} \\ | \\ R(\lambda_2) \\ | \\ a \end{array} \begin{array}{c} \text{---} \\ | \\ R'' \\ | \\ \text{---} \\ | \\ f \end{array} \begin{array}{c} c \\ \text{---} \\ | \\ d \\ \text{---} \\ | \\ e \end{array} \right)$$

Example for choice of a, b, c, d, e, f .

$$Z \left(\begin{array}{c} \nearrow \\ \diagdown \\ \lambda_1 \\ \diagup \\ \searrow \\ \lambda_2 \end{array} \right) = \text{wt} \left(\begin{array}{c} \nearrow \\ \diagdown \\ \nearrow \\ \diagup \\ \searrow \\ \nearrow \end{array} \right) + \text{wt} \left(\begin{array}{c} \nearrow \\ \diagdown \\ \searrow \\ \diagup \\ \nearrow \\ \searrow \end{array} \right)$$

this is left-hand side of YBE. for this choice of a, b, c, d, e, f .

$$= R'' \left(\begin{array}{c} \nearrow \\ \diagdown \\ \searrow \\ \diagup \end{array} \right) \cdot SE(\lambda_1) \cdot SW(\lambda_2) + R'' \left(\begin{array}{c} \searrow \\ \diagdown \\ \nearrow \\ \diagup \end{array} \right) \cdot EW(\lambda_1) \cdot NS(\lambda_2)$$

2^6 cases = 64. $\frac{1}{2}$ empty. 32 cases... 32 equations "quadratic in λ "

$$\text{RHS} = Z \left(\begin{array}{c} \nearrow \\ \diagdown \\ \searrow \\ \diagup \\ \nearrow \\ \searrow \end{array} \right)$$

GOAL: Find R'' weights in b-vertex model that solve all 32 cases simultaneously.

$$= \text{wt} \left(\begin{array}{c} \nearrow \\ \diagdown \\ \nearrow \\ \diagup \\ \searrow \\ \nearrow \end{array} \right) + \text{wt} \left(\begin{array}{c} \searrow \\ \diagdown \\ \nearrow \\ \diagup \\ \nearrow \\ \searrow \end{array} \right) = R'' \left(\begin{array}{c} \nearrow \\ \diagdown \\ \searrow \\ \diagup \end{array} \right) \cdot EW(\lambda_2) \cdot NS(\lambda_1) + R'' \left(\begin{array}{c} \searrow \\ \diagdown \\ \nearrow \\ \diagup \end{array} \right) \cdot SW(\lambda_2) \cdot SE(\lambda_1)$$

↑ note same boundary conditions

If we have a solution R'' to YBE, how does it prove commutativity of transfer matrices?

Pictorial proof · Start with $Z \left(\begin{array}{c} \rightarrow 1 \rightarrow \\ \rightarrow 2 \rightarrow \\ \dots \\ \rightarrow \end{array} \right)$

Step Claim 1.

$$Z \left(\begin{array}{c} \rightarrow 1 \rightarrow \\ \rightarrow 2 \rightarrow \\ \dots \\ \rightarrow \end{array} \right) = \text{wt} \left(\begin{array}{c} \nearrow \\ \searrow \\ \nearrow \\ \searrow \end{array} \right) \cdot Z \left(\begin{array}{c} \rightarrow 1 \rightarrow \\ \rightarrow 2 \rightarrow \\ \dots \\ \rightarrow \end{array} \right)$$

Step 2 $\longrightarrow \parallel$

Use YBE to conclude...

$$Z \left(\begin{array}{c} \rightarrow 2 \rightarrow \\ \rightarrow 1 \rightarrow \\ \dots \\ \rightarrow \end{array} \right) \begin{array}{l} \text{YBE} \\ = \text{again} \end{array} \dots \begin{array}{l} \text{YBE} \\ = \text{again} \end{array} = Z \left(\begin{array}{c} \rightarrow 2 \rightarrow \\ \rightarrow 1 \rightarrow \\ \dots \\ \rightarrow \end{array} \right) \text{wt} \left(\begin{array}{c} \nearrow \\ \searrow \\ \nearrow \\ \searrow \end{array} \right)$$

so these transfer matrices commute!

Algebraic interpretation

$R \in \text{End}(V_{(1)} \otimes V_{(2)})$

vertical strand - one copy of V
horizontal strand - other copy of V .

3 strands.

← coeff. in $\text{End}(V \otimes V \otimes V)$ vs

↓ as endoms
 $R_{12} R_{13} R_{23} = R_{23} R_{13} R_{12}$

in our case: $R''_{12} R(\lambda_1)_{13} R(\lambda_2)_{23}$

pictorial pf is given algebraically in 7.5.3 of Chari-Pressley.
 $= R(\lambda_2)_{23} R(\lambda_1)_{13} R''_{12}$
